ABSTRACT

In this paper, maximum likelihood estimation have been obtained for two Weibull populations under joint type II censored scheme, which generalize results of Balakrishnan and Rasouli (2008). Moreover, approximate confidence region are also discussed and compared with two Bootstrap confidence regions. A numerical illustration for these new results is given.

Keywords: Weibull distribution; Joint type-II censoring; Maximum likelihood estimation; Approximate confidence; Bootstrap intervals; Coverage probabilities.

1. INTRODUCTION

There are various types of censored data to be dealt with in the analysis of lifetime experiments see Lawless (2003). Almost all of these types of data are concerned with the one-sample problems. But, there are situations in which the experimenter plans to compare different populations. In such problems, the joint censoring scheme has been suggested in the literature. As mentioned by Rasouli and Balakrishnan (2010), a joint censoring scheme is quite useful in conducting comparative lifetime test of products coming from different units within the same facility.

More precisely, suppose that the products are being produced by two lines under the same facility. Two independent samples of sizes \(m\) and \(n\) are selected from these lines and put simultaneously on a life testing experiment. Then, to save time and money, the experimenter follows a joint censoring scheme and terminates the life testing when a certain number of failures (say, \(r\)) occur.

Suppose that \(X_1, \ldots, X_m\), the lifetimes of \(m\) specimens of product \(A\), are i.i.d. random variables from distribution function \(F(x)\) and density function \(f(x)\), and \(Y_1, \ldots, Y_n\), the lifetimes of \(n\) specimens of product \(B\), are i.i.d. random variables from distribution function \(G(x)\) and density function \(g(x)\). Further, suppose \(W_{(1)} < W_{(2)} < \ldots < W_{(N)}\) denote the order statistics of the \(N = m + n\) random variables \(\{X_1, \ldots, X_m; Y_1, \ldots, Y_n\}\). Then, under the joint type-II censoring scheme, the observable data consist of \((Z, W)\), where \(W = (W_{(1)}, W_{(2)}, \ldots, W_{(r)})\), with \(r (1 \leq r < N)\) being a pre-fixed integer, and \(Z = (Z_1, \ldots, Z_r)\) with \(z_i = 1\) or \(0\) according as \(w_i\) is from an \(X\)- or \(Y\)-failure.

Letting \(M_r = \sum_{i=1}^{r} Z_i\) denote the number of \(X\)-failures in \(W\) and \(N_r = \sum_{i=1}^{r} (1 - Z_i) = r - M_r\) (i.e., the number of \(Y\)-failures in \(W\)), the likelihood of \((Z, W)\) is given by Balakrishnan and Rasouli (2008) as:

\[
L = C \prod_{i=1}^{r} \left[ \left( \frac{f(w_i)}{\bar{f}(w_i)} \right)^{Z_i} \left( \frac{g(w_i)}{\bar{G}(w_i)} \right)^{1-Z_i} \right]^a \left( \frac{\bar{G}(w_i)}{G(w_i)} \right)^{a-b},
\]

where \(\bar{F} = 1 - F, \bar{G} = 1 - G\) are the survival functions of the two populations and \(C = \frac{m! n!}{(m - m_r)!(n - n_r)!}\).

Balakrishnan and Rasouli (2008) developed likelihood inference for the parameters of two exponential populations under joint type-II censoring. They developed inferential methods based on maximum likelihood estimates (MLE) and compared their performance with those based on some other approaches such as Bootstrap. Shafay et al. (2013) derived the Bayesian inference for the unknown parameters of two exponential populations under joint type II censoring.
developed with the use of squared-error, linear-exponential and general entropy loss functions. The problem of predicting the future failure times, both point and interval prediction, based on the observed joint type-II censored data is obtained; see also Rasouli and Balakrishnan (2010) for a generalization of their results to progressive type-II censoring. Balakrishnan and Feng (2014) generalized Balakrishnan and Rasouli (2008) and Shafay et al. (2013) works by considering a jointly type II censored sample arising from $h$ independent exponential populations. Finally, Ashour and Abo-Kasem (2014) derived Bayesian and non-Bayesian estimators for two generalized exponential populations under joint type II censored scheme.

Succeeding section deals with the computational procedure to obtain the MLEs of $\beta_1, \beta_2, \theta_1$ and $\theta_2$. The asymptotic variance covariance matrix and approximate confidence region based on the asymptotic normality of the maximum likelihood estimators have been obtained in section 3. While section 4 is describes the various bootstrap confidence intervals. All estimators are not in close closed forms, therefore, numerical examples are considered to illustrate the proposed estimators in section 5. Last section includes a brief conclusion.

2. MAXIMUM LIKELIHOOD ESTIMATORS

Suppose that the two populations are Weibull distribution with density and distribution functions as

$$f_j(x) = \beta_j x^{\beta_j-1} \exp\left(-\frac{x}{\theta_j}\right)^{\beta_j},$$

and

$$F_j(x) = 1 - \exp\left(-\frac{x}{\theta_j}\right)^{\beta_j},$$

$\beta_j, \theta_j > 0, x > 0$, for $j = 1, 2$, respectively where $\beta_j$ are the shape parameters and $\theta_j$ are the scale parameters. In this case, the likelihood function in (1) becomes

$$L(\beta_1, \beta_2, \theta_1, \theta_2, w, z) = \left(\frac{\beta_1}{\theta_1}\right)^{w_1} \left(\frac{\beta_2}{\theta_2}\right)^{w_2} x^{w_1} \exp\left(-\frac{x}{\theta_1}\right)^{w_1 \beta_1} \left[\exp\left(-\frac{x}{\theta_2}\right)^{w_2 \beta_2}\right]^{x-x_2} \times \left[\exp\left(v_1\right)^{\gamma_n-x_2}\right]^{m-n} \times \left[\exp\left(v_2\right)^{\gamma_n-x_2}\right]^{n-m},$$

where

$$w_1 = \frac{w}{\beta_1}, w_2 = \frac{w}{\beta_2}, \gamma_n = \frac{w}{\beta_1}, \gamma_n = \frac{w}{\beta_2}$$

and $v_1 = \frac{v}{\beta_1}$ and $v_2 = \frac{v}{\beta_2}$.

Therefore, to obtain the MLE’s of $\beta_j$ and $\theta_j$ we find the first derivatives of the natural logarithm of the likelihood function (2) with respect to $\beta_j$ and $\theta_j$, and equating them to zero, we get the following four equations

$$\frac{\partial \ln L}{\partial \beta_1} = \sum_{i=1}^m z_i \left[\ln \left(\frac{\beta_1}{\theta_1}\right) - \beta_1 \ln \left(\frac{x_i}{\theta_1}\right) - (m - m_i) \left(\gamma_n\right)^{\beta_1} \ln \left(\gamma_n\right)\right] = 0,$$

$$\frac{\partial \ln L}{\partial \beta_2} = \sum_{i=1}^m (1 - z_i) \left[\ln \left(\frac{\beta_2}{\theta_2}\right) - \beta_2 \ln \left(\frac{x_i}{\theta_2}\right) - (n - n_i) \left(\gamma_n\right)^{\beta_2} \ln \left(\gamma_n\right)\right] = 0,$$

$$\frac{\partial \ln L}{\partial \theta_1} = \left(\frac{\beta_1}{\theta_1}\right)^{w_1} \left[\exp\left(-\frac{x}{\theta_1}\right)^{w_1 \beta_1} \left[\exp\left(-\frac{x}{\theta_2}\right)^{w_2 \beta_2}\right]^{x-x_2} \times \left[\exp\left(v_1\right)^{\gamma_n-x_2}\right]^{m-n} \times \left[\exp\left(v_2\right)^{\gamma_n-x_2}\right]^{n-m} \right] = 0,$$

and

$$\frac{\partial \ln L}{\partial \theta_2} = \left(\frac{\beta_2}{\theta_2}\right)^{w_2} \left[\exp\left(-\frac{x}{\theta_1}\right)^{w_1 \beta_1} \left[\exp\left(-\frac{x}{\theta_2}\right)^{w_2 \beta_2}\right]^{x-x_2} \times \left[\exp\left(v_1\right)^{\gamma_n-x_2}\right]^{m-n} \times \left[\exp\left(v_2\right)^{\gamma_n-x_2}\right]^{n-m} \right] = 0$$

where $\hat{\beta}_j = \frac{w}{\hat{\beta}_j}, \hat{\theta}_j = \frac{w}{\hat{\theta}_j}, \hat{\gamma}_n = \frac{w}{\hat{\gamma}_n}$ and $\hat{v}_j = \frac{w}{\hat{v}_j}$.

By solving (3), we get the following MLEs of $\hat{\beta}_j$ and $\hat{\theta}_j$ for $j = 1, 2$ as

$$\hat{\beta}_1 = \frac{(m - m_i) \left(\gamma_n\right)^{\beta_1} - \sum_{i=1}^m z_i \ln \left(\gamma_n\right)}{m - m_i},$$

and

$$\hat{\theta}_1 = \frac{\left(\gamma_n\right)^{\beta_1} - \sum_{i=1}^m (1 - z_i) \ln \left(\gamma_n\right)}{m - m_i},$$

$$\hat{\beta}_2 = \frac{(n - n_i) \left(\gamma_n\right)^{\beta_2} - \sum_{i=1}^m (1 - z_i) \ln \left(\gamma_n\right)}{n - n_i}$$

which can be solved by using an iterative numerical method, and

$$\hat{\theta}_2 = \frac{(n - n_i) (1 - z_i) \ln \left(\gamma_n\right)}{n - n_i}$$

Not that for $\beta_1 = 1$ we obtain MLEs based on a jointly type-II censored sample from two exponential populations which introduced by Balakrishnan and Rasouli (2008).

Remark: From the MLEs in (4), it is evident that when $m_i = \sum_{i=1}^m z_i = 0$ or $r$, $\hat{\beta}_j$ or $\hat{\theta}_j$ do not exist, respectively. Hence, the MLEs in (4) are only conditional MLEs, conditioned on $1 \leq m_r \leq r - 1$.

3. APPROXIMATE CONFIDENCE INTERVALS

The approximate asymptotic variance-covariance matrix for $\beta_j$ and $\theta_j$ for $j = 1, 2$ can be obtained by inverting the information matrix with the elements that are negative of the expected
values of the second order derivatives of logarithms of the likelihood functions. Cohen (1965) concluded that the approximate variance covariance matrix may be obtained by replacing expected values by their MLEs. Now, the Fisher information matrix associated with $\beta_j$ and $\theta_j$ is defined as:

$$I(\beta, \beta_1, \theta, \theta_1) = E \left[ \begin{array}{ccc} \frac{\partial^2 \ln L}{\partial \beta \partial \beta} & 0 & \frac{\partial^2 \ln L}{\partial \beta \partial \theta} & 0 \\ 0 & \frac{\partial^2 \ln L}{\partial \beta_1 \partial \beta} & 0 & \frac{\partial^2 \ln L}{\partial \beta_1 \partial \theta} \\ \frac{\partial^2 \ln L}{\partial \theta \partial \beta} & 0 & \frac{\partial^2 \ln L}{\partial \theta \partial \theta} & 0 \\ 0 & \frac{\partial^2 \ln L}{\partial \theta_1 \partial \beta} & 0 & \frac{\partial^2 \ln L}{\partial \theta_1 \partial \theta} \end{array} \right],$$

where

$$\frac{\partial^2 \ln L}{\partial \beta} = -\frac{m}{\beta_0} \sum_{i=1}^n z_i \left( (y_i)^{\beta} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta} \left( \frac{1}{\theta_i} \right),$$

$$\frac{\partial^2 \ln L}{\partial \theta} = -\frac{n}{\beta_0} \sum_{i=1}^n \left( (y_i)^{\beta_0} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta_0} \left( \frac{1}{\theta_i} \right),$$

$$\frac{\partial^2 \ln L}{\partial \beta \partial \theta} = m \left( \sum_{i=1}^n \left( (y_i)^{\beta_0} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta} \left( \frac{1}{\theta_i} \right) \right) - (m - m_i) \left( \sum_{i=1}^n \left( (y_i)^{\beta_0} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta_0} \left( \frac{1}{\theta_i} \right) \right),$$

and

$$\frac{\partial^2 \ln L}{\partial \theta_1 \partial \theta_1} = \frac{n}{\theta_0} \sum_{i=1}^n \left( (y_i)^{\beta} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta} \left( \frac{1}{\theta_1} \right)^2 - (n - n_i) \left( \sum_{i=1}^n \left( (y_i)^{\beta} \ln(y_i) + (m - m_i) \ln(y_i) \right) \left( \frac{1}{y_i} \right)^{\beta} \left( \frac{1}{\theta_1} \right)^2 \right).$$

Using the asymptotic normality of the MLEs, we can express the approximate $100(1 - \alpha)\%$ confidence intervals for $\beta_j, \theta_j$ for $j = 1, 2$.

Suppose that $\hat{\delta}$ is the MLE of the parameter vector $\delta = (\beta_1, \beta_2, \theta_1, \theta_2)$. Denote the Fisher information matrix corresponding to $\delta$ by $I_{\delta}$ and $\phi = \lim_{n \to \infty} n I_{\delta}^{-1}$. Then, $\hat{\delta}$ is asymptotically normal distributed (see Serfling (1980)), i.e.,

$$\sqrt{n}(\hat{\delta} - \delta) \sim N(0, \phi).$$

In particular, let

$$\left( \hat{S}_{\beta j} \right)^2 = \hat{\theta}_{(j,j)}/n, \quad j = 1, 2,$n

where $\hat{\theta}_{(j,j)}$, $j = 1, 2$, are the $(j, j)$ elements in the matrix $\hat{\phi} = n \hat{I}_{\hat{\delta}}^{-1}$ and $\hat{I}_{\hat{\delta}}$ is the estimator of $I_{\hat{\delta}}$. Therefore, asymptotic normality confidence intervals of $\delta_j$, $j = 1, 2$, with confidence level $100(1 - \alpha)\%$ are given by

$$\hat{\beta} = z_{(1 - \alpha)/2} \hat{I}_{\hat{\delta}}^{-1} \hat{S}_{\beta}, \quad \hat{\theta} = z_{(1 - \alpha)/2} \hat{I}_{\hat{\delta}}^{-1} \hat{S}_{\theta}, \quad j = 1, 2,$n

where $z_{(1 - \alpha)/2}$ denotes the upper $(1 - \alpha)/2$ percentage point of the standard normal distribution.

Also, an approximate $100(1 - \alpha)\%$ simultaneous confidence interval (SCI) for $(\beta_1, \beta_2, \theta_1, \theta_2)$, using the Bonferroni method, can be obtained as

$$\hat{\beta} = z_{(1 - \alpha)/4} \hat{I}_{\hat{\delta}}^{-1} \hat{S}_{\beta}, \quad \hat{\theta} = z_{(1 - \alpha)/4} \hat{I}_{\hat{\delta}}^{-1} \hat{S}_{\theta}, \quad j = 1, 2$$

4. BOOTSTRAP INTERVALS

In this section, we present several bootstrap methods to construct confidence intervals for $\beta_j, \theta_j$ for $j = 1, 2$, viz., Studentized-t interval (Boot-t) and Percentile interval (Boot-p) (see Efron (1982) and Efron and Tibshirani (1994) for details).

a) Bootstrap Percentile Interval Procedure (Boot-p)

The bootstrap percentile method defines the lower and upper bounds of the confidence intervals just using the $100(1 - \alpha/2)\%$ quantiles of the empirical bootstrap distribution of $\hat{\beta}_j$ and $\hat{\theta}_j$, $j = 1, 2$ respectively. In particular:

1. Compute the MLE $(\hat{\beta}_j, \hat{\theta}_j)$ of $(\beta_j, \theta_j)$ based on two Weibull populations using joint type II censored sample $(w, z)$.

2. Use $(\hat{\beta}_j, \hat{\theta}_j)$ to generate a bootstrap joint type II censored sample $(w^*, z^*)$ and compute the bootstrap estimate of $(\beta_j, \theta_j)$, say $(\hat{\beta}_j, \hat{\theta}_j)$, based on this bootstrap sample.

3. Repeat step 2 $B$ times to have $\hat{\beta}_j^{(1)}, \hat{\beta}_j^{(2)}, ..., \hat{\beta}_j^{(B)}$ and $\hat{\theta}_j^{(1)}, \hat{\theta}_j^{(2)}, ..., \hat{\theta}_j^{(B)}$.

4. Arrange $\hat{\beta}_j^{(1)}, \hat{\beta}_j^{(2)}, ..., \hat{\beta}_j^{(B)}$ and $\hat{\theta}_j^{(1)}, \hat{\theta}_j^{(2)}, ..., \hat{\theta}_j^{(B)}$ in ascending order and obtain $\hat{\beta}_j^{(1)}, \hat{\beta}_j^{(2)}, ..., \hat{\beta}_j^{(B)}$ and $\hat{\theta}_j^{(1)}, \hat{\theta}_j^{(2)}, ..., \hat{\theta}_j^{(B)}$.

5. A two-sided $100(1 - \alpha)\%$ percentile bootstrap confidence interval for $(\beta_j, \theta_j)$, say $[\hat{\beta}_j^*, \hat{\beta}_j^*]$, and $[\hat{\theta}_j^*, \hat{\theta}_j^*]$ is given by
\((\hat{\beta}_j, \hat{\beta}'_j) = (\hat{\beta}^{(B = 2)}_j, \hat{\beta}^{(B = 1 - a/2)}_j)\) and 

\((\hat{\theta}_j, \hat{\theta}'_j) = (\hat{\theta}^{(B = 2)}_j, \hat{\theta}^{(B = 1 - a/2)}_j)\)

b) Studentized-t Interval Procedure (Boot-t)

The Boot-t confidence intervals estimators are computed according to the following steps:

1. Compute the t-statistic \(T_{\beta_j} = (\hat{\beta}_j - \hat{\beta}) / S_{\hat{\beta}_j}\) and \(T_{\theta_j} = (\hat{\theta}_j - \hat{\theta}) / S_{\hat{\theta}_j}\), where \(S_{\hat{\beta}_j}\) and \(S_{\hat{\theta}_j}\) are the bootstrap versions.

2. Repeat steps 1–2 \(B\) times and obtain \(T_{\beta_j}^{(1)} \ldots T_{\beta_j}^{(2)} \ldots T_{\beta_j}^{(B)}\) and \(T_{\theta_j}^{(1)} \ldots T_{\theta_j}^{(2)} \ldots T_{\theta_j}^{(B)}\).

3. Arrange \(T_{\beta_j}^{(1)} \ldots T_{\beta_j}^{(2)} \ldots T_{\beta_j}^{(B)}\) and \(T_{\theta_j}^{(1)} \ldots T_{\theta_j}^{(2)} \ldots T_{\theta_j}^{(B)}\) in ascending order and obtain \(T_{\beta_j}^{[1]} \ldots T_{\beta_j}^{[2]} \ldots T_{\beta_j}^{[B]}\) and \(T_{\theta_j}^{[1]} \ldots T_{\theta_j}^{[2]} \ldots T_{\theta_j}^{[B]}\).

4. A two-sided \((1 - \alpha)\%\) bootstrap-t confidence interval for \((\beta_j, \theta_j)\) say \([\hat{\beta}_j, \hat{\beta}'_j]\) and \([\hat{\theta}_j, \hat{\theta}'_j]\), is given by

\[
(\hat{\beta}_j + T_{\beta_j}^{[1]} \tilde{S}_{\hat{\beta}_j}, \hat{\beta}_j + T_{\beta_j}^{[1]} \tilde{S}_{\hat{\beta}_j}), \quad j = 1, 2,
\]

and

\[
(\hat{\theta}_j + T_{\theta_j}^{[1]} \tilde{S}_{\hat{\theta}_j}, \hat{\theta}_j + T_{\theta_j}^{[1]} \tilde{S}_{\hat{\theta}_j}), \quad j = 1, 2,
\]

5. NUMERICAL ILLUSTRATION

It clear that, there are no explicit solutions for obtaining new estimators. Therefore artificial data, numerical solution and computer facilities are needed. The main object of this section is to illustrate numerically most of the new theoretical result obtained in the previous two sections.

5.1 Illustrative Example

In this sub section we present Proschan’s Data (1963) which gives failure times (in hours) of the air-conditioning systems of Boeing 720 jet airplanes “7913” and “7914”. It is observed that the failure distribution of the air-conditioning system for each of the planes was well approximated by an exponential distribution, where \(m = 24\) and \(n = 27\), we ran the various joint censoring schemes on this dataset with \(r = 20\) and 30. The data are presented in table 1.

Table 1: Failure times of air-conditioning systems in two airplanes

5.2 Monte Carlo simulation

A simulation study was conducted in order to evaluate the performance of MLEs and also all the confidence intervals discussed in the preceding sections. We considered different sample sizes for the two populations as m = 15, 20, 30, 50, 80 and n = 15, 20, 30, 50, 80 and different choices for r = 17, 20, 24, 28, 32, 40, 50, 60, 80, 90, 100, 120,140. We also chose the parameters (\beta, \beta, \theta, \theta) to be (4.5, 2.5, 2, 3). For these cases, we computed the MLEs, root mean squared errors \( \sqrt{MSE} \) and the 95% approximate confidence intervals for (\beta, \beta, \theta, \theta) and the corresponding coverage probabilities. We repeated this process 5000 times and computed the average values of all the estimates. The average value of the MLEs (\beta, \beta, \theta, \theta) and (\sqrt{MSE}) are presented for some small, moderate and large values of m and n.

Table 5: The average value of the MLEs (\beta, \beta, \theta, \theta) and (\sqrt{MSE}) for small, moderate and large values of m, n and r

\beta_1 = 4.5, \beta_2 = 2.5, \theta_1 = 2 and \theta_2 = 3
6. CONCLUSIONS

In this paper, the MLEs for the unknown parameters of two Weibull distributions has been discussed based on a joint type-II censored sample. We obtained the MLEs of the parameters and found corresponding Fisher information matrix. Also, we studied three approximate methods, Asymptotic Normality, Bootstrap-t and parametric Bootstrap percentile procedures for constructing intervals for the parameters. The MLEs have then been compared through a Monte Carlo simulation study and a numerical example has also been presented to illustrate all the inferential results established here. The computational results show that the MLEs have a moderate bias when the essential sample size is small even when the sample sizes \( m \) and \( n \) are not small. This bias also seems to affect the approximate confidence intervals based on normality as they are not centered properly in this case. However, the bias of the MLEs becomes negligible when \( r \) increases, as is evident from. According to the simulation study, when the sample sizes of two populations, \( n \) and \( m \), and the total number of failures \( r \), are large, the estimators’ biases are small and the confidence intervals have desirable coverage probabilities. Also, we observed that the approximate better than the two bootstrap methods often perform as well as each other.
